An approach to achieving optimized complex sheet inflation under constraints

Abstract

Sheet inflation is an enhanced and more general version of the classic pillowing procedure[1] used to modify hexahedrdal meshes. The flexibility of sheet inflation makes it a valuable tool for hex mesh generation, modification and topology optimization. However, it is still difficult to generate self-intersecting sheet within a local region while assuring the mesh quality. This paper proposes an approach to achieving optimized complex sheet inflation under various constraints. To determine a qualified inflatable quad set, the approach firstly constructs the boundary loop and the initial quad set by using max-flow-min-cut algorithm, and then improves the quality of the initial quad set by a chord-based optimization method. Our approach can generate complex sheets that intersect themselves more than once and guarantee the quality of the resultant mesh. We successfully apply this approach to mesh matching and mesh boundary optimizing.

Keywords: hex mesh; sheet inflation; mesh optimization; mesh modification; mesh matching

1. Introduction

In finite element analysis, hex meshes are usually preferred to tetrahedral meshes due to higher accuracy, faster convergence and lighter storage[2, 3]. Therefore, many researchers have been committed to the research of hex meshing for decades. Although there has been tremendous progress in this area, perfect solutions are still eluding for hex mesh generation, modification and topological optimization. The main reason for the difficulties is the inherent global connectivity which makes any local modification often inevitably propagate to the whole mesh[4, 5, 6, 7].

In recent years, sheet operations attract more and more attention and have been applied in different situations for their effectivity in dealing with global structures. The most common sheet operations include sheet inflation, sheet extraction, dicing and column collapse. Unlike other operations that only deal with existing sheets, sheet inflation can be utilized to create new ones with various shapes and topologies, making it irreplaceable in hex mesh generation, especially in topological modification and optimization. The common procedures of sheet inflation are shown in Fig. 1.

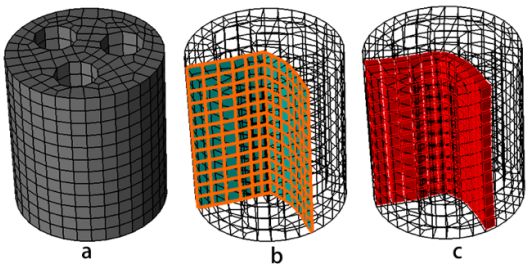

Figure 1: Sheet inflation procedures: (a) the original hex mesh; (b) the quad set; (c) the new sheet inflated from the quad set.

Due to its versatile ability to create various types of sheets with different shapes and topologies, it is critical for sheet inflation to be controllable in order to meet various mesh modification demands. In practice, the controllability can be fulfilled by allowing the user to setup constraints on the mesh to guide the inflation process. These constraints are usually specified by a set of boundary edges and a set of hexahedra. The former determines the positions where the new sheet should appear on the mesh boundary, and the latter delimits the region where the new sheet can propagate. As shown in Fig. 2(b), a set of boundary edges(green) and a set of hex(yellow) are specified to control the shape and position of the new sheet. One satisfactory sheet is shown in Fig. 2(d).

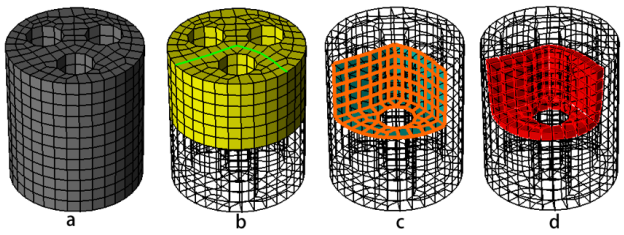

Figure 2: Sheet inflation under user-specified constraints: (a) the original hex mesh; (b) the user-specified boundary edges (green) and hex set (yellow); (c) the internal quad set; (d) the new sheet.

As seen in Fig. 1 and Fig. 2, the quad set is critical to sheet inflation since it determines both the position and topology of the sheet to be inflated. Therefore, to achieve the qualified sheet inflation, the main task, which is also the most difficult, is to find an internal quad set that satisfies the constraints. As shown in Fig. 2, after the user specifies the constraints in Fig. 2(b), the most critical step to generate the qualified sheet is to determine the internal quad set within the specified hex set that intersects with the mesh boundary exactly at the specified edges, as shown in Fig. 2(c).

In recognizing the importance of sheet inflation, many re-

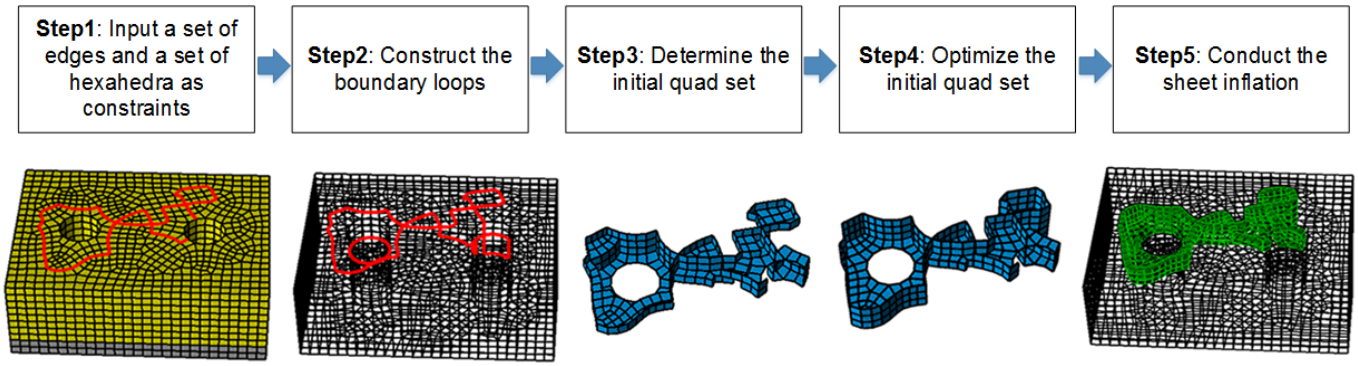

Figure 3: Overview of the approach.

searchers have been investigating algorithms for decades and have achieved great progress. Mitchell et al. proposed the Pillowing algorithm to deal with the doublet problem[1]. This algorithm involves inflating a new sheet guided by a hex set called shrinking set. Its simplicity and effectiveness makes Pillowing prevalent in mesh modification, especially in mesh quality improvement. Although it can be adapted to satisfy simple constraints, the Pillowing lacks the ability to generate complex sheets such as self-intersecting sheets.

Suzuki et al. introduced a method to construct interior sheet surfaces when the boundary dual cycles are given[8]. They used this method to firstly construct dual structures and then deduce the primal hex meshes from these dual structures. While in the paper they illustrated the topological structures of sheet surfaces in the dual space, particularly self-intersecting sheet surfaces, they didn't mention how to determine the quad set and generate the corresponding sheets on the primal hex mesh.

Staten et al. proposed the General Sheet Inflation method which explained in detail how to do sheet inflation on hex meshes when boundary mesh edges are specified[9]. This method can create normal, self-touching and self-intersecting sheets. However, determining the quad sets for sheet inflation in this method seems to rely on the sweeping structures of the mesh. Meanwhile it is not clear whether the method can create self-intersecting sheets within a local region.

Chen et al. proposed a new approach to inflate sheets when conducting mesh matching on complex interfaces[10]. This method firstly constructs the boundary loop of the quad set, and then determines the interior quad set. Although it can locally generate self-intersecting sheets under constraints, it allows the sheets to intersect themselves once at most. Meanwhile, the optimization method it applies on quad set cannot guarantee the quality improvement.

Despite these achievements, to inflate complex sheets under various constraints, especially to generate self-intersecting sheets within a local region, is still very difficult. Furthermore, how to assure the mesh quality for complex sheet inflation is also a challenging problem. In this paper we propose a new approach to achieving complex sheet inflation. By firstly determining the boundary loop and then utilizing the max-flow-min-cut algorithm, we construct an initial quad set that fulfills all the constraints. By applying a chord-based optimization method, we improve the quality of the quad set and thus the mesh quality after sheet inflation is guaranteed.

The rest of this paper is organized as below: we will show the outline of the approach in the second chapter, explain the procedures of constructing the boundary loops of quad sets in the third chapter, provide the details of the determination and optimization of the initial quad set in the fourth and fifth chapters respectively, and then give some results in the sixth chapter and list conclusions and future work in the last chapter.

2. Overview of the Approach

In this paper, an approach is proposed to achieving complex sheet inflation under various constraints while assuring the mesh quality. It takes a set of boundary mesh edges and a set of hexahedra as input. The edges and hexahedra specify the boundary position and local region of the sheet. Under these constraints, it constructs a qualified quad set and then creates the new sheet as output. To avoid the difficulty of determining a qualified inflatable quad set directly, our approach involves three major steps: (a) determining the boundary loops for the quad set that satisfy the boundary constraints; (b) constructing the initial quad set based on the boundary loops; (c) optimizing the initial quad set. Figure 3 shows the overview of our approach.

Our approach needs to solve two critical problems. The first problem is how to construct the valid boundary loop and initial quad set satisfying various boundary constraints. Boundary constraint specified by the user can be a loop or just a set of edges, be non-self-intersecting or intersecting itself more than once. The second problem is how to effectively optimize the initial quad set when a global optimal result can hardly be reached.

To solve these two problems, our basic ideas are:

1. We use path searching and max-flow-min-cut algorithms to construct the valid boundary loop and initial quad set that meet the various boundary constraints. In accordance with the inherent characteristics of valid boundary loops and quad sets, loops can be formed by the path searching algorithm if the boundary constraints are not loops, and

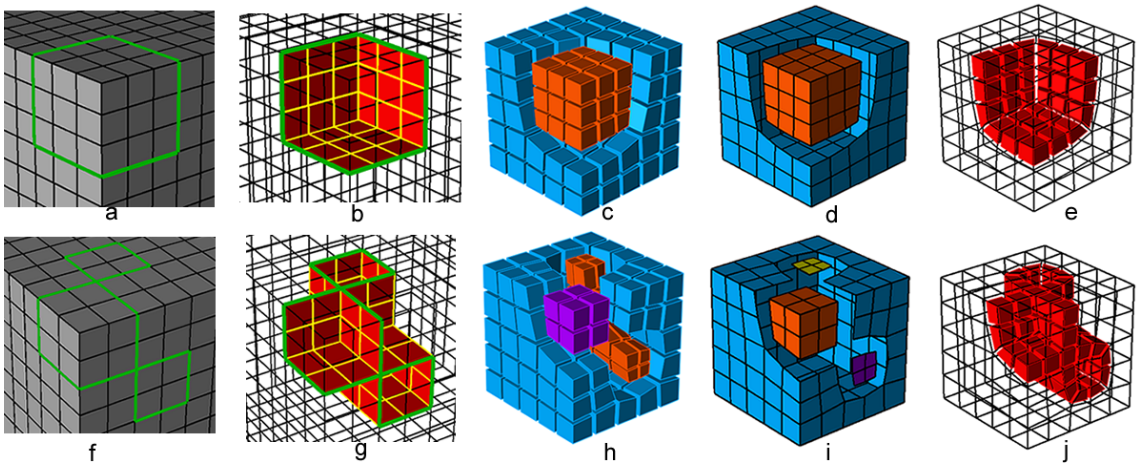

Figure 4: Characteristics of valid boundary loops: (a) a non-self-intersecting boundary loop; (b) the non-self-intersecting quad set; (c) two hex sets separated by the quad set; (d) two boundary quad sets separated by the boundary loop; (e) the new non-self-intersecting sheet; (f) a self-intersecting boundary loop; (g) the self-intersecting quad set; (h) three hex sets separated by the quad set; (i) four boundary quad sets separated by the boundary loop; (j) the new self-intersecting sheet.

intersecting lines on the quad set can also be determined by the path searching algorithm. The valid boundary loop and initial quad set can be effectively determined by the max-flow-min-cut algorithm due to the fact that the determination of these structures on the mesh is analogous to finding a cut set on a graph;

2. We optimize the initial quad set by optimizing its chords. The chords, the dual structures of the quad set, are more global than individual edges while less constrained than the whole quad set. By optimizing the chords, we can effectively improve the quality of the quad set while avoiding the difficulty in optimizing the quad set as a whole.

In the following sections specific details of the major steps are provided.

3. Determination of the Boundary Loops

It is quite difficult to find a qualified quad set satisfying all the constraints directly. The quad set's boundary loop is accordingly constructed at first. This section firstly discusses the characteristics of valid boundary loops and quad sets, and then presents the method to construct a valid boundary loop under the boundary constraints.

By observation of the structures of valid quad sets and the process of sheet inflation, an inflatable quad set and its boundary loop have two characteristics:

1. An inflatable quad set separates its local hex set into $2 + N$ subsets, where N stands for how many times the quad set intersects itself. For example, the non-self-intersecting quad set in Fig. 4(b) separates the local hex set into two parts (Fig. 4(c)). The self-intersecting quad set in Fig. 4(g) separates the local hex set into 3 subsets (Fig. 4h). Meanwhile, the boundary loop of the quad set separates the boundary of the local hex set into $2 + n$ subsets, where n is the number of self-intersecting nodes on the boundary

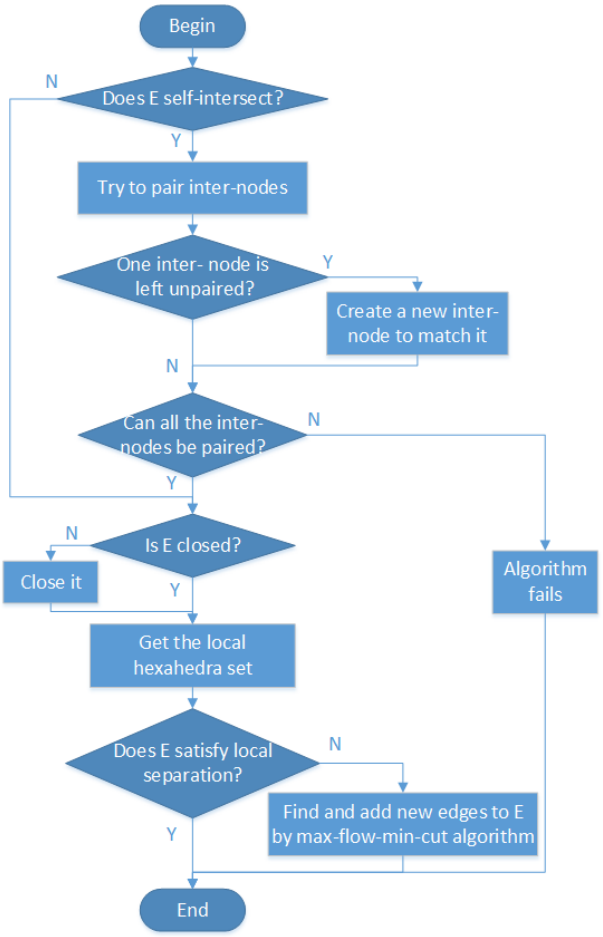

Figure 5: Flowchart of the determination of boundary loops.

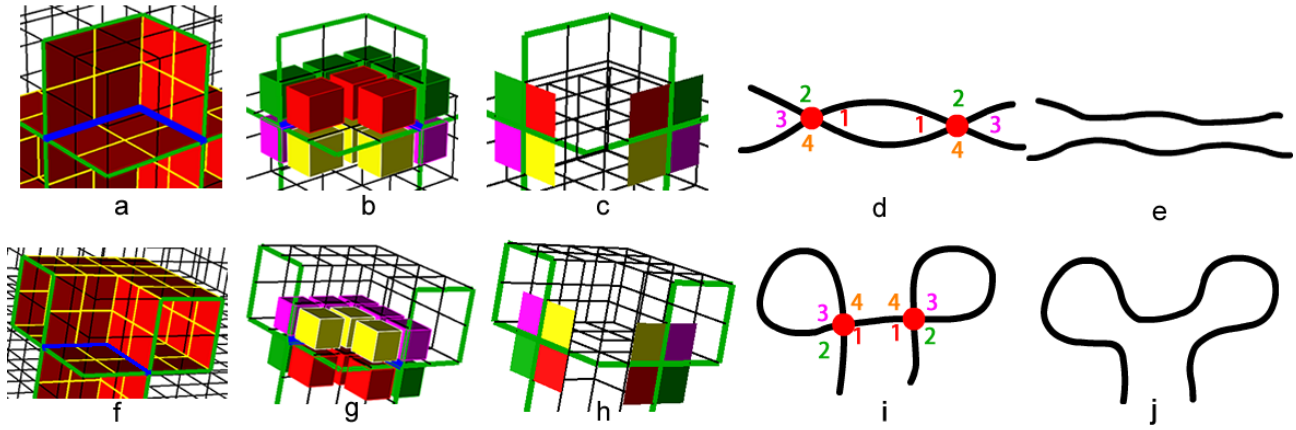

Figure 6: Two local templates for pairing intersecting nodes: (a) the 1st local intersecting structure of the quad set; (b) int-4-hex-sets around the 1st local intersecting structure of the quad set; (c) the associated local structure of the boundary loop; (d) the 1st template; (e) intersecting nodes are resolved after pairing; (f) the 2nd local intersecting structure of the quad set; (g) int-4-hex-sets around the 2nd local intersecting structure of the quad set; (h) the associated local structure of the boundary loop; (i) the 2nd template; (j) intersecting nodes are resolved after pairing.

loop. The non-self-intersecting boundary loop in Fig. 4(a) separates the boundary of the local hex set into two subsets (Fig. 4(d)), and the self-intersecting boundary loop in Fig. 4(f) separates the boundary of the local hex set into 4 subsets (Fig. 4(i)).

2. Intersecting nodes on the boundary loop can be grouped into pairs. An intersecting line on the quad set can be found between two nodes in each pair.

The first characteristic, which is also called local separation, is necessary for a quad set to be inflatable, because the sheet inflation operation is actually done by separating the hex subsets and filling the gaps with new hexahedra, as shown in Fig. 4(c), Fig. 4(e), Fig. 4h and Fig. 4(j). It also indicates that the boundary loops must be closed otherwise new hexahedra on the mesh boundary will not be correctly created. The second characteristic also indicates that each intersecting node on the boundary loop needs another intersecting node to be paired in order to determine an intersecting line.

Based on the above analysis, we check whether the specified constraint edges are eligible to be a valid boundary loop. If not, we use the path searching algorithm and max-flow-min-cut algorithm to determine a valid boundary loop. The flowchart of the determination of boundary loops is shown in Fig. 5. The rest of this section will provide detailed description about the method of the determination of boundary loops.

3.1. Pairing Intersecting Nodes

For self-intersecting quad sets, the intersecting lines play a very important role in defining the structures of the quad sets. The intersecting nodes on the boundary lines need to be paired in order to construct the intersecting line between each pair of intersecting nodes. It needs decision which two can be paired when there are more than two intersecting nodes. Improper pairing of intersecting nodes will result in non-orientable surface with very poor quality or even no surface at all[8]. Based on the observation of the structures of quadrilateral sets, we bring out two templates for pairing intersecting nodes. By recursively applying these two templates, a proper pairing between intersecting nodes can be achieved.

These two templates come from two simple self-intersecting quad sets as shown in Fig. 6(a) and Fig. 6(f). These two quad sets both have one intersecting line and two intersecting nodes on their boundary loops. Topological structures of their boundary loops form the two templates as shown in Fig. 6(d) and Fig. 6(i). If a part of the boundary loop has the same topological structure as either of the two templates, there must be a quad set with the same topological structure of the corresponding simple self-intersecting quad set. This template-based pairing method thus can effectively avoid improper pairing result mentioned in [8]. To recursively find next pair of intersecting nodes, the local topological structures are modified accordingly as shown in Fig. 6(e) and Fig. 6(j).

Some structures near the intersecting lines or intersecting nodes are very important for determining the quad set. The hexahedra adjacent to the intersecting lines are separated into four subsets by the local structures of quad sets, as shown in Fig. 6(b) and Fig. 6(g). These hex subsets are called int-4-hex-sets of the intersecting line. The associated local structures of boundary loops are shown in Fig. 6(c) and Fig. 6(h). The quads in same color mean they are adjacent to the same int-4-hex-set. The numbers in different colors on the two templates in Fig. 6(d) and Fig. 6(i) indicate the corresponding int-4-hex-sets.

Two examples in Fig. 7 are presented to explain how to pair intersecting nodes by these two templates.

The pairing process for the 1st example is shown in Fig. 8. Firstly the intersecting nodes A and B are paired by the 1st template. After topological structure is modified, C and D are also paired by the 1st template.

The pairing process for the 2nd example is shown in Fig. 9. Firstly the intersecting nodes A and B are paired by the 2nd template. After topological structure is modified, the nodes C and D are paired by the 1st template.

After recursively applying these two templates, if there is still

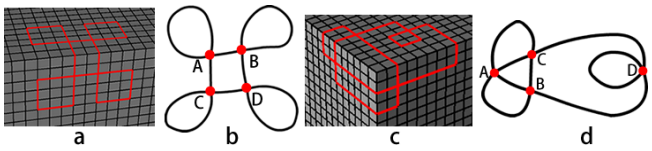

Figure 7: Two examples of pairing intersecting nodes: (a) the boundary loop of the 1st example; (b) the topological structure of the boundary loop of the 1st example; (c) the boundary loop of the 2nd example; (d) the topological structure of the boundary loop of the 2nd example.

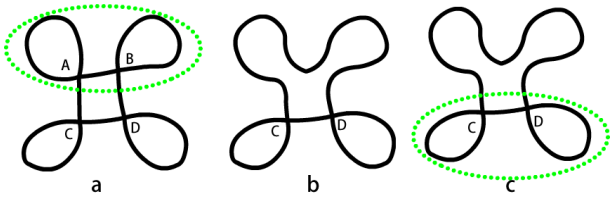

Figure 8: The pairing process of the 1st example: (a) node A and B are paired; (b) node A and B are resolved; (c) node C and D are paired.

one intersecting node left unpaired, we use the templates to create a new intersecting node at a appropriate position to be paired with this intersecting node. For example, in Fig. 10(a), the intersecting node A is unpaired. We use the 2nd template to create a new intersecting node B to be paired with A as shown in Fig. 10(b).

Our algorithm would fail if some intersecting nodes are unable to be paired by the two templates. These boundary loops usually determine non-orientable quad sets[8] which will largely degenerate the mesh quality after sheet inflation. Therefore we do not handle such kind of boundary loops in this paper.

3.2. Forming Closed Boundary Loops

The ability to do local separation requires the constraint edges to form closed loops. Sometimes the constraint edges, which are specified by the user according to specific mesh modification requirements, may not be closed loops. When this happens, we need to close the constraint edges by adding new edges on the mesh boundary. This is done by connecting the dangling edges on the constraint edges using the A* path searching algorithm.

A* path searching is a one-source-one-target path searching algorithm which runs very efficiently. When applying A* algorithm, in addition to considering the count of mesh edges on the path, we also take the angles between adjacent edges on the path into consideration in order to get a smooth path. Figure

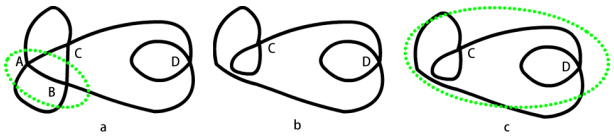

Figure 9: The pairing process of the 2nd example: (a) node A and B are paired; (b) node A and B are resolved; (c) point C and D are paired.

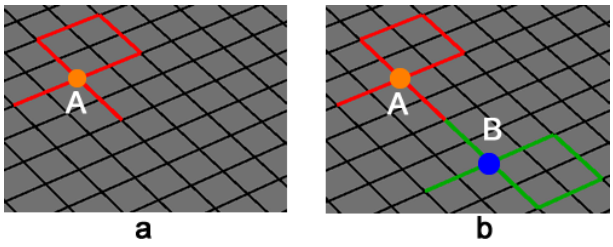

Figure 10: Handling of the situation when single intersecting node is unpaired: (a) intersecting node A is unpaired; (b) intersecting node B is created to be paired with A.

11(b) shows the result when the angles between adjacent edges are not considered, and Fig. 11(c) shows a better result when the angles are taken into consideration.

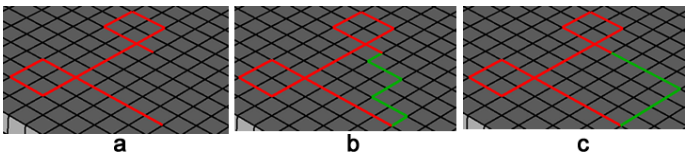

Figure 11: Closing the boundary loop: (a) the unclosed boundary loop; (b) new edges determined by A* algorithm without considering the turning angles; (c) new edges determined by A* algorithm considering the turning angles.

3.3. Making the Boundary Loop Able to Do Local Separation

After previous sections, the constraint edges specified by the user become a closed boundary loop with intersecting nodes being paired. According to the discussion in the beginning of Section 3, a valid boundary loop should be able to do local separation. Sometimes the closed boundary loop may fail to do local separation due to the existence of through holes on the hex mesh. To fix that, we use the max-flow-min-cut algorithm to add necessary edges to the boundary loop to make it able to do local separation. Suppose the boundary loop is E, the algorithm flowchart is illustrated in Fig. 12.

The following example illustrates the process. Figure 13(a) shows the hex mesh containing a through hole and the boundary loop E (red). To check whether E is able to do local separation, we firstly get E's adjacent hex set H (Fig. 13(b)) and iteratively add H's adjacent hexahedra to H and test whether the new boundary of H can be separated by E into two subsets until reaching the maximum iteration times (Fig. 13(c)). However, E is still unable to do local separation on H since there are still only one quad set (blue in Fig. 13(d)) on H's boundary. Hence, we need to use the max-flow-min-cut algorithm to add other necessary mesh edges to E to make it able to do local separation.

Max-flow-min-cut algorithm is an effective and efficient tool to find the minimal cut set in a directed graph. As shown in Fig. 14(a), to use the max-flow-min-cut algorithm, a directed graph should be constructed with an s node and a t node, and the weights of the edges should also be set before calculation.

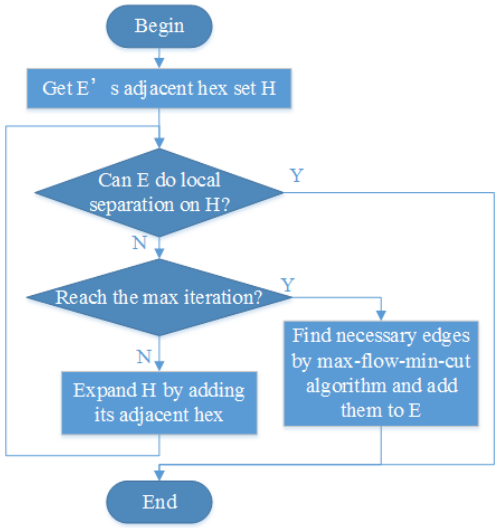

Figure 12: Flowchart of the process of making the boundary loop able to do local separation.

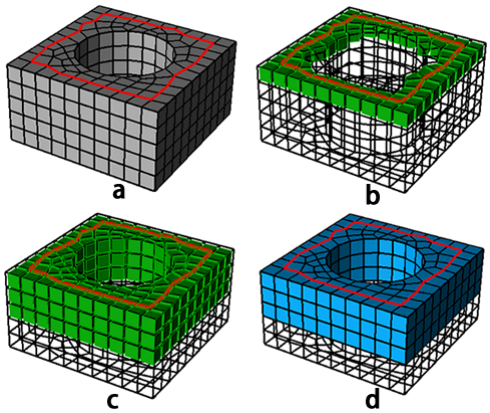

Figure 13: An example of boundary loops that are unable to do local separation: (a) the boundary loop E; (b) E's adjacent hexahedra H(green); (c) expand H by iteratively adding its adjacent hexahedra; (d) E still cannot separate H's boundary into two subsets when reaching maximum expanding iteration times.

The algorithm will find a minimal cut set that determines the max flow from s to t.

If we take the boundary of H as a graph where the nodes stand for a quad or a quad set and the edges stand for the adjacency relationship between the quads or quad sets, then to be able to do local separation is similar to find a cut set on this graph. Hence, the max-flow-min-cut algorithm can be used to help us to find necessary edges to make the boundary loop satisfy the local separation.

To use the algorithm, we need to construct the directed graph at first, including constructing the s and t nodes and deciding the edges' weights. As the current boundary loop E must be part of the final boundary loop, the two quad sets on its two sides just can be the s and t nodes as shown in Fig. 14(b). Since all of the edges on the final boundary loop should be on the boundary of the hex mesh, the quads shared by H and the rest of the hex mesh, which is shown as Q_{in} in Fig. 14(b), should be accordingly grouped into a single node in the graph to guarantee that Q_{in} won't be separated by the min cut. Similarly, in order to forbid the mesh edges on sharp CAD model edges to be added in to the boundary loop, which usually results in poor mesh quality, we group the quads sharing these mesh edges into a single node, e.g. q_2 and q_3 in Fig. 14(c).

After constructing the nodes, we assign weights to the graph edges according to how many mesh edges are shared by the two nodes. For example, q_1 in Fig. 14(c) shares two edges with node t, so the weight of the directed edges in the graph between q_1 and t is 2. All of the edges in the graph are bi-directional except the edges adjacent to s and t.

The final directed graph is shown in Fig. 14(d). After calculation, new edges are found as shown in Fig. 14(e), and now E is able to do local separation after adding these new edges as shown in Fig. 14(f).

When a self-intersecting boundary loop is unable to do local separation, we also need to apply max-flow-min-cut algorithm to find necessary new edges to make it able to do local separation. The procedures are quite similar to non-self-intersecting boundary loop discussed previously. We treat a self-intersecting boundary loop as several non-self-intersecting boundary loops and handle each of them individually. The self-intersecting boundary loop in Fig. 15(a) consists of three sub loops $loop_1$, $loop_2$ and $loop_3$. The local hex set is shown in Fig. 15(b). Due to the existence of three through holes on the hex mesh, the boundary loop is unable to do local separation. After applying max-flow-min-cut algorithm to $loop_1$ and $loop_3$, new edges are found as shown in Fig. 15(c).

4. Determination of the Initial Quad Set

This section provides specific details of the determination of the initial quad set based on the boundary loop. The intersecting lines are firstly constructed according to the pairing of the intersecting nodes. The initial quad set is then constructed using the max-flow-min-cut algorithm. Since the boundary loops satisfy the boundary constraints and the max-flow-min-cut algorithm is conducted within the local region specified by the user, the initial quad set fulfills all the constraints.

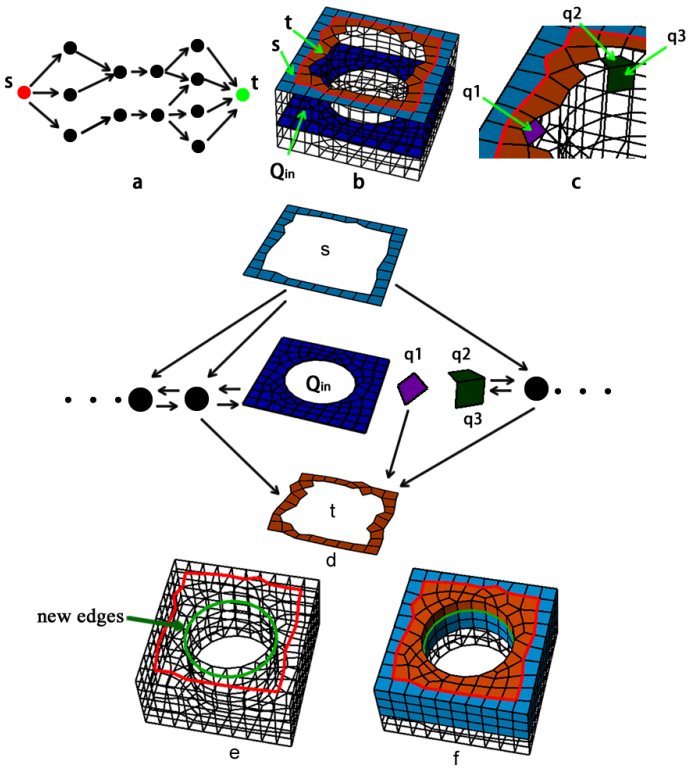

Figure 14: Using max-flow-min-cut algorithm to find necessary edges for local separation: (a) directed graph used for ordinary max-flow-min-cut problem; (b) the quad sets on E's two sides can be s and t nodes; (c) q_1 shares two edges with t, q_2 and q_3 share an edge on the geometric hard edge; (d) the directed graph for max-flow-min-cut algorithm; (e) new edges are found (green); (f) E is able to do local separation after adding new edges.

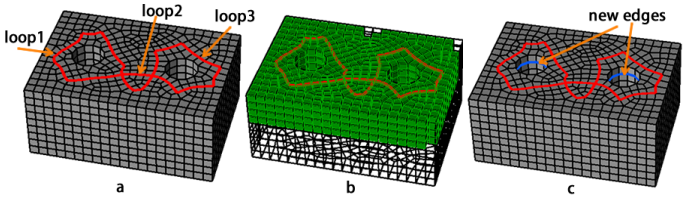

Figure 15: Making self-intersecting boundary loop able to do local separation: (a) the self-intersecting boundary loop with three sub loops; (b) the local hex set; (c) new edges (blue) are found by using max-flow-min-cut algorithm.

4.1. Determination of Intersecting Lines

Intersecting lines are very important for defining the structures of self-intersecting quad sets. Before determining the initial quad set, we need to construct the intersecting lines first. In Section 3.1 the two templates not only make two intersecting nodes be paired but also setup the corresponding relationships between the int-4-quad-sets of the two intersecting nodes. In this section, we use this information to construct the intersecting lines and the int-4-hex-sets of these intersecting lines.

The following example shows the process of constructing the intersecting line and its int-4-hex-sets. In Fig. 16(a), the blue nodes are two intersecting nodes paired by the 1st template (in this example they can also be paired by the 2nd template), and the numbers and different colors denote the correspondence between the int-4-quad-sets of the two points. We use A* algorithm to determine the intersecting line between the two intersecting nodes. Similar to Section 3.2, in order to get a smooth path, we take the turning angles between adjacent edges in the path into consideration while appling the A* searching. The intersecting line is shown in Fig. 16(b). Next, we get all the hexahedra adjacent to the intersecting line, and use the correspondence between the int-4-quad-sets to construct the int-4-hex-sets as shown in Fig. 16(c).

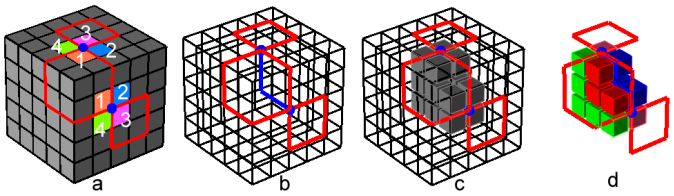

Figure 16: Process of constructing the intersecting line and its int-4-hex-sets: (a) two intersecting nodes paired by the 1st template; (b) the intersecting line determined by A* algorithm; (c) the hexahedra adjacent to the intersecting line; (d) the int-4-hex-sets of the intersecting line.

4.2. Determination of Initial Quad Set by Max-flow-min-cut Algorithm

After constructing the intersecting lines and their int-4-hex-sets, we now construct the initial quad set. The idea is similar to that mentioned in Section 3.3, we convert the problem from being able to do local separation to acquiring min cut on a graph. If we see the hexahedra as nodes and the adjacency between the hexahedra as edges of the graph, the quad set is actually a cut set of the graph. Hence, max-flow-min-cut algorithm can be used to efficiently get a quad set that is able to do local separation. This section provides specific details about this process.

As the boundary loop separates the boundary of the local hex set into $2+n$ subsets (n is the number of intersecting nodes), we can get $2+n$ hex sets that are adjacent to these $2+n$ quad sets. From these $2+n$ hex sets and the int-4-hex-sets of the intersecting lines, we merge hex sets that share common hexahedra. This will result in $2+N$ hex sets (N is the number of intersecting lines). We then apply the max-flow-min-cut algorithm multiple times to get the initial quad set. The pseudo-codes are provided in Algorithm 1.

Algorithm 1 Determination of the Initial Quad Set

Input: The boundary loop L and the local hex set H_{local};
Output: The initial quad set Q_{init};

n = the count of self-intersecting nodes on L;
N = the count of intersecting lines;
Get the quad subsets on the boundary of H_{local} as $Q_{bound} = \{Q_{b1}, Q_{b2}, \cdots, Q_{b2+n}\}$;
$H_{bound} = \{H_{b1}, H_{b2}, \cdots, H_{b2+n}\}$ where H_i is the hex set adjacent to $Q_i, i = 1, 2, \cdots, 2+n$;
$H_{int} = \{H^1_{in1}, H^2_{in1}, H^3_{in1}, H^4_{in1}, \cdots, H^1_{inN}, H^2_{inN}, H^3_{inN}, H^4_{inN}\}$ where $\{H^1_{ini}, H^2_{ini}, H^3_{ini}, H^4_{ini}\}$ is the int-4-hex-sets of the ith intersecting line;
$H_{merge} = H_{bound} \cup H_{int}$;
while $\exists H_{mi}, H_{mj} \in H_{merge}, i \neq j$ that $H_{mi} \cap H_{mj} = \emptyset$ **do**
    Merge H_{mi} and H_{mj};
end while
$Q_{init} = \emptyset$;
for each $H_{mi} \in H_{merge}$ **do**
    $H_{rest} = \bigcup\{H_{merge} - H_{mi}\}$;
    Let H_{mi} be the s node and H_{rest} be the j node;
    Perform the max-flow-min-cut algorithm and get the quad set Q_i;
    $Q_{init} = Q_{init} \cup Q_i$;
end for

Two examples are provided to illustrate the procedures of Algorithm 1. The first example is a non-self-intersecting boundary loop as shown in Fig. 17. n and N are both 0 for this example. The two quad subsets on the boundary of the local hex set H are Q_{b1} and Q_{b2} as shown in Fig. 17(c). We get the two hex sets adjacent to Q_{b1} and Q_{b2} as H_{b1} and H_{b2} (Fig. 17(d)). We construct the directed graph by taking H_{b1} as s node and H_{b2} as t node, taking other hexahedra as normal nodes, and assigning weights to the edges according to the number of quads shared by two hex sets. After running the max-flow-min-cut algorithm, we get the initial quad set Q_{init} as shown in Fig. 17(e).

The second example is a self-intersecting boundary loop as shown in Fig. 18. The boundary loop (red in Fig. 18(a)) intersects itself once, hence $n = 2, N = 1$. Firstly we get the int-4-hex-sets $i4h_1$-$i4h_4$(Fig. 18(b)). The boundary of the local hex set H is separated into Q_{b1}-Q_{b4}(Fig. 18(c)), and the hex sets adjacent to these quad subsets are H_{b1}-H_{b4} (Fig. 18(d) and Fig. 18(e)). Therefore $H_{merge} = H_{int} \cup H_{bound} = \{i4h_1, \cdots, i4h_4, H_{b1}, \cdots, H_{b4}\}$. After merging, $H_{merge} = \{H_{m1}, H_{m2}, H_{m3}\}$ (Fig. 18(f) and Fig. 18(g)). We then conduct the max-flow-min-cut algorithm twice. For the first time, we take H_{m1} as s node and $H_{m2} \cup H_{m3}$ as t node (Fig. 18(h)), and get the quad set Q_1 (Fig. 18(i)). For the second time, we take H_{m2} as s node and $H_{m1} \cup H_{m3}$ as t node (Fig. 18(j)), and get the quad set Q_2 (Fig. 18(k)). Finally the initial quad set is $Q_{init} = Q_1 \cup Q_2$ (Fig. 18(l)).

5. Optimization of the Initial Quad Set

Although the initial quad set determined by previous section satisfies all the constraints specified by the user, the quality of the mesh after sheet inflation is usually not good enough. In this paper we propose a new optimization method for the quad set based on the quad set's dual structures. In this section we discuss the details of this optimization method.

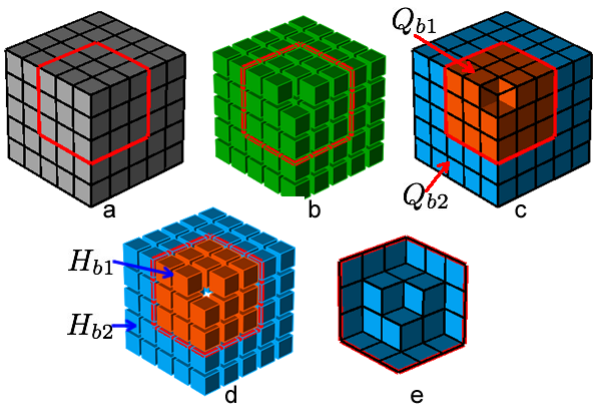

Figure 17: Process of the determination of the initial quad set from a non-intersecting boundary loop: (a) the non-intersecting boundary loop; (b) the local hex set; (c) the two boundary quad subsets Q_{b1}(orange) and Q_{b2}(blue); (d) two hex sets H_{b1}(orange) and H_{b2}(blue); (e) the initial quad set Q_{init}.

5.1. Quality Evaluation of the Quad Set

In a hex mesh, the valence of a mesh edge stands for the count of its adjacent quads. A mesh edge is called a regular edge if it is inside the mesh or on the mesh boundary and its valence equals 4 or 3 respectively. Otherwise the edge is called an irregular edge. The irregular degree is the difference of valences between one edge and its corresponding regular edge. Suppose e stands for an edge and v_e stands for it valence, the irregular degree of e is computed as Equation 1.

$$ID(e) = \begin{cases} \|v_e - 4\| & \text{if } e \text{ is inside the mesh,} \\ \|v_e - 3\| & \text{if } e \text{ is on the mesh boundary.} \end{cases} \quad (1)$$

Staten et al. showed that the edge valence has direct impact on the mesh quality in [11]. Therefore in this paper we use the edges' valences and irregular degree to evaluate the quality of the quad set.

When creating new sheets, different quad sets have different impact on the quality of the mesh. In Fig. 19(a), before sheet inflation, $ID(e_1) = 0$; after sheet inflation, e_1 is splitted into two edges e_2 and e_3 and $ID(e_2) + ID(e_3) = 0$ as shown in Fig. 19(c). However, if Q_2 (Fig. 19(d)) is inflated, although e_4 is a regular edge, the two edges splitted from e_4 are irregular edges as shown in Fig. 19(f), and $ID(e_5) + ID(e_6) = 2$. The inherent reason for the difference of irregular degrees is that Q_1 and Q_2 separate the adjacent hex sets into different configurations as shown in Fig. 19(b) and Fig. 19(e).

Suppose e is an edge on quad set Q, and Q separates e's adjacent hexahedra into two subsets H_1 and H_2, then the variation between the irregular degrees of e and two edges splitted from e can be computed by Equation 2. $\|H_1\|$ and $\|H_2\|$ represent the

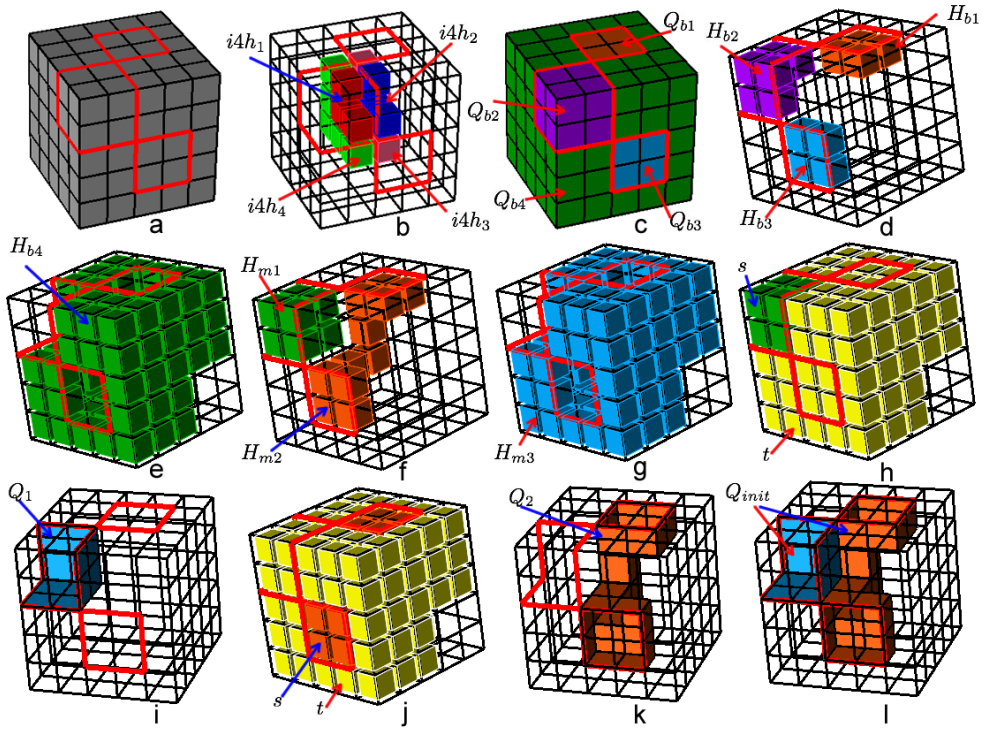

Figure 18: Process of the determination of the initial quad set from a self-intersecting boundary loop: (a) the self-intersecting boundary loop; (b) the int-4-hex-sets $i4h_1$-$i4h_4$ of the intersecting line; (c) the four quad subsets Q_{b1}-Q_{b4} on the boundary of the local hex set separated by the boundary loop; (d) the hex sets H_{b1}-H_{b3} adjacent to Q_{b1}-Q_{b3} respectively; (e) the hex set H_{b4} adjacent to Q_{b4}; (f) the hex set H_{m1} merging from $i4h_1$ and H_{b2} and H_{m2} merging from $i4h_3$, H_{b1} and H_{b3}; (g) the hex set H_{m3} merging from $i4h_2$, $i4h_4$ and H_{b4}; (h) take H_{m1} as s node and $H_{m2} \cup H_{m3}$ as t node; (i) the quad set Q_1 determined by the max-flow-min-cut algorithm; (j) take H_{m2} as s node and $H_{m1} \cup H_{m3}$ as t node; (k) the quad set Q_2 determined by the max-flow-min-cut algorithm; (l) the initial quad set $Q_{init} = Q_1 \cup Q_2$.

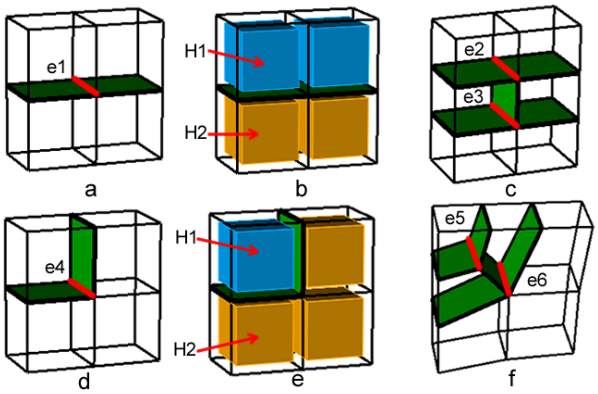

Figure 19: Different impacts on the mesh quality of different quad sets: (a) quad set Q_1(green) and one of its mesh edges e_1(red); (b) the hex set adjacent to e_1 is separated into two subsets H_1 and H_2 by Q_1; (c) e_1 is splitted into two edges e_2 and e_3 after inflation; (d) quad set Q_2 and one of its mesh edges e_4; (e) the hex set adjacent to e_4 is separated into two subsets H_1 and H_2 by Q_2; (f) e_4 is splitted into two edges e_5 and e_6 after inflation.

numbers of hexahedra in H_1 and H_2 respectively. A negative ΔV_e means the mesh quality near e has been improved by the inflation, otherwise the mesh quality becomes worse.

$$\Delta V_e = \|H_1\| + \|H_2\| - ID(e) \tag{2}$$

If Q is non-self-intersecting, $E = \{e_1, e_2, \cdots, e_n\}$ is the set of edges on Q where n is the count of the edges, Q's variation of irregular degrees ΔV_Q can then be computed by Equation 3.

$$\Delta V_Q = \sum_{i=1}^{n} \Delta V_{e_i} \tag{3}$$

5.2. Chord-based Optimization of the Quad Set

To improve the quality of the quad set, it needs to adjust the structure of the quad set to make it contain as less edges with large variation of irregular degrees as possible. It is, however, not a trivial task since any changes applied on one edge will inevitably impact its adjacent edges. Theoretically, if we evaluate all the possible quad sets then we can find the optimal quad set with least variation of irregular degrees. Nevertheless it is almost impossible due to the large searching space. Chen et al. proposed an optimization method which locally handles concave or convex edges one by one[10]. This method avoids the difficulty of global optimization by handling the irregular edges on the quad set in a greedy-based manner. However, it cannot guarantee the mesh quality due to the interaction between edges

on the quad set, and sometimes it may be even not convergent. In this paper, we propose an optimization method based on the dual structure of the quad set. Our method not only avoids the difficulty in global optimization, but also guarantees the mesh quality after sheet inflation.

On a quad mesh, starting from an edge, we can recursively get all the edges that are topologically parallel to this edge. These edges and the adjacent quads form a chord, the dual structure of the quad set[4, 12]. Similar to the quad mesh, the quad set used for sheet inflation also consists of chords. All of the mesh edges on the boundary loop pairwise belong to one chord. For example, in Fig. 20(b), e_1 and e_2 belong to the chord c_1, and e_3 and e_4 belong to the chord c_2. The difference between a quad mesh and a quad set for sheet inflation is that there is a sheet associated with each chord on the quad set. For example, in Fig. 20(c), e_3, e_4 and their chords are contained in the sheet s (red). This relationship reveals that if two edges on the boundary loop belong to a same chord, then we can find other chords connecting these two edges within the corresponding sheet.

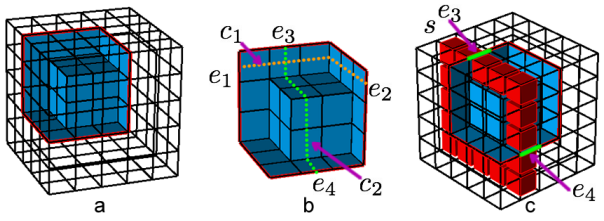

Figure 20: The chords of the quad set: (a) the quad set; (b) two chords c_1 and c_2 on the quad set; (c) the sheet s that contains e_3 and e_4.

We improve the quality of the quad set by iteratively improving the quality of the chords that contain the edges on the boundary loop. The chords are neither too constrained as the whole quad set nor too local as one single concave or convex edge. By optimizing the chords, we can effectively improve the quality of the quad set while avoiding the difficulty of optimizing the quad set as a whole. Suppose the quad set is Q and its edge set is E, the details of the optimization procedures are explained:

1. Divide the edges on the boundary loop into groups according to whether they are in the same sheet. For example, e_3 and e_4 are grouped in Fig. 21(a), and e_1 - e_4 are grouped in Fig. 22(a);
2. Select a group of edges that have not been processed. Get all of the edges in the corresponding sheet and the quads adjacent to these edges. These edges and quads compose the searching space for new chords that connect these edges. Suppose the edge group is $g = \{e_3, e_4\}$, Fig. 21(b) shows the edges that are in the same sheet of g and the adjacent quads;
3. Since the edges in the group pairwise connect to one chord, we use A* algorithm to search for the new chords. While searching, we take the edges' variation of irregular degrees into consideration. For example, in Fig. 21(c), there are three quads adjacent to q_1. If we select q_2 or q_4 as the next forward step, the variation of irregular degrees of e_5 will be 2; if we select q_3 as the next forward step, the variation of irregular degrees e_5 becomes 0. Hence we select q_3. The new chord connecting e_3 and e_4 is shown in Fig. 21(d). If there are more than two edges in the group, it needs deciding which two edges should be paired. For example, four edges e_1 - e_4 in Fig. 22(b) are in the same group. If we connect e_1 and e_3 and get the new chord c_3 (blue in Fig. 22(c)), then e_2 and e_4 cannot be connected without intersecting with c_3 which is not allowed for keeping the quad set valid as shown in Fig. 22(d). So we search new chords between e_1 and e_4, e_2 and e_3. The two new chords are shown in Fig. 22(e);
4. The new chords and the original chords encompass a hex set on the sheet. For example, the hex set h in Fig. 21(e) is encompassed by the two chords c_2 an c_4, and the hex set h in Fig. 22(f) is encompassed by the four chords c_1,c_2,c_4 and c_5. We get the boundary quad set Q_h of h, and let Q be the symmetric difference between Q and Q_h, i.e. $Q = Q \cup Q_h - Q \cap Q_h$. The updated Q is shown in Fig. 21(f) and Fig. 21(g);
5. Repeat the process of Step 2-4 until all of the edge groups are handled. The final quad sets for the two examples are shown in Fig. 21(g) and Fig. 22(g).

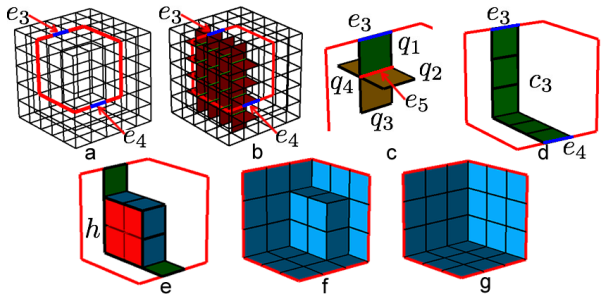

Figure 21: The 1st example of the quad set optimization: (a) two edges e_3 and e_4 on the boundary loop; (b) the edges on the sheet (green) and adjacent quads (red); (c) q_1's three adjacent quads q_2, q_3 and q_4; (d) the new chord connecting e_3 and e_4; (e) the hex set h encompassed by the two chords; (f) Q is updated by getting the symmetric difference between Q and Q_h; (g) the final quad set.

The variation of irregular degrees ΔV_Q of the initial quad set in Fig. 20(a) is 42. After optimization, the variation of irregular degrees of the quad set in Fig. 21(g) $\Delta V'_Q$ becomes 18, which is 24 smaller than ΔV_Q.

The variation of irregular degrees ΔV_Q of the initial quad set in Fig. 22(a) is 76, and it becomes 56 after optimization which is 20 smaller.

6. Examples

We implement our approach in C++ on a 32-bit Windows 7 platform, using Visual Studio 2010. The approach has been tested on different meshes under various constraints. This section presents two practical applications of the approach: one is complex sheets generation for mesh matching and the other one

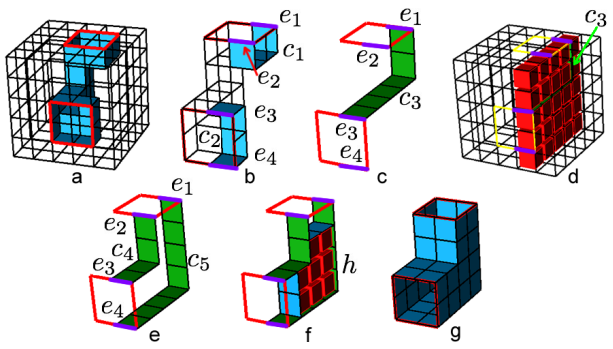

Figure 22: The 2nd example of the quad set optimization: (a) the initial quad set; (b) e_1-e_4 on the same sheet and two chords c_1 and c_2; (c) the new chord c_3 connecting e_1 and e_3; (d) e_2 and e_4 cannot be connected by a chord without intersecting c_3; (e) the two new chords c_4 and c_5; (f) the hex set h encompassed by the four chords; (g) Q is updated by getting the symmetric difference between Q and Q_h.

is the quality improvement for the mesh boundary by reducing high node valences.

6.1. Complex Sheets Generation for Mesh Matching

Mesh matching is an algorithm to convert non-conforming interfaces to conforming ones by sheet operations[11, 10]. Our approach in this paper can be used in mesh matching to locally generate complex sheets that intersect themselves multiple times, which cannot be done in these previous works. In Fig. 23, there is an unmatched chord on the interface of hex mesh 2 in Fig. 23(b). A new sheet needs to be created to match it on hex mesh 1 under the constraints shown in Fig. 23a (H is the volumetric constraints).

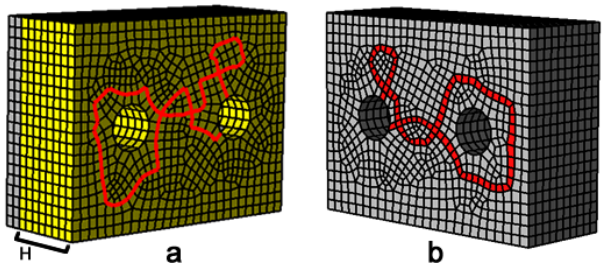

Figure 23: Complex sheet inflation is needed for mesh matching: (a) the constraints for sheet inflation on mesh 1; (b) the unmatched chord(red) on mesh 2.

Under the constraints, we construct the boundary loop as shown in Fig. 24. Since the constraint edges contain three intersecting nodes, a new intersecting node is created as shown in Fig. 24(b). By running the max-flow-min-cut algorithm, new edges are found, enabling the boundary loop to do local separation. The final boundary loop is shown in Fig. 24(e).

Intersecting lines are then constructed, as well as the int-4-hex-sets as shown in Fig. 25(a) and Fig. 25(b). Then we get the merged hex sets in Fig. 25(c) and the initial quad set in Fig. 25(d). The variation of irregular degrees of the initial quad set is 478. By contrast, the final quad set is much better after

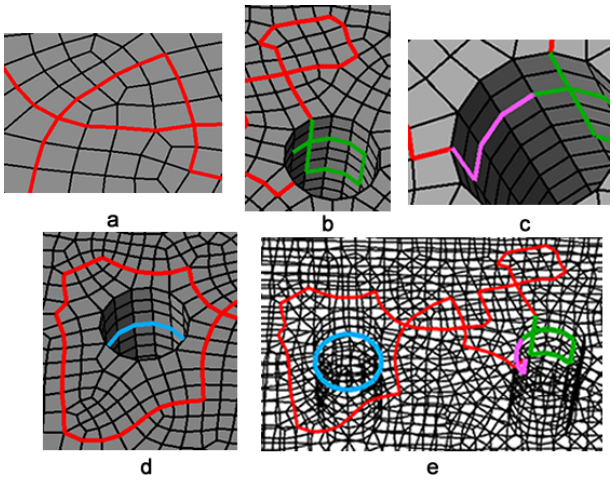

Figure 24: Determination of the boundary loop: (a) the two intersecting nodes are paired; (b) a new intersecting node is created; (c) the boundary loop is closed; (d) new edges are determined by the max-flow-min-cut algorithm; (e) the final boundary loop.

optimization as shown in Fig. 25(e) whose variation of irregular degrees is reduced to 351.

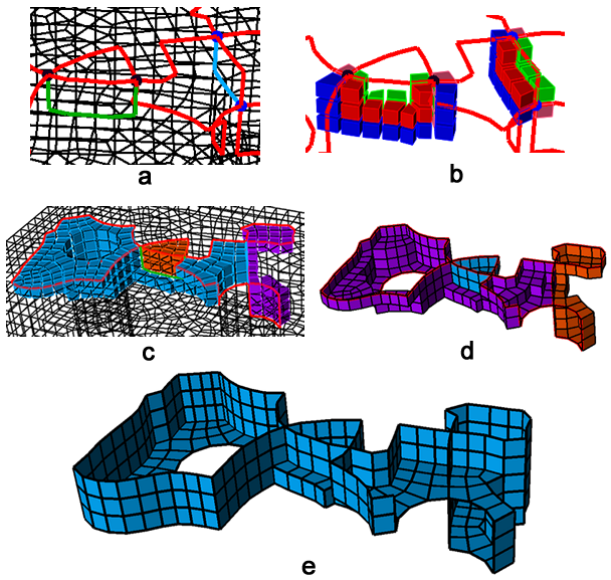

Figure 25: Determination of the quad set: (a) constructing the intersecting lines; (b) the int-4-hex-sets; (c) the merged hex sets; (d) the initial quad set; (e) the optimized quad set.

The new sheet is inflated from the quad set as shown in Fig. 26.

6.2. High Edge Valences Reduction

In hex meshes, the elements in the area near the boundary are usually very important for finite element analysis[13]. Meanwhile, the node valence and edge valence are critical for the quality of the quad mesh and hex mesh respectively[14, 11, 15].

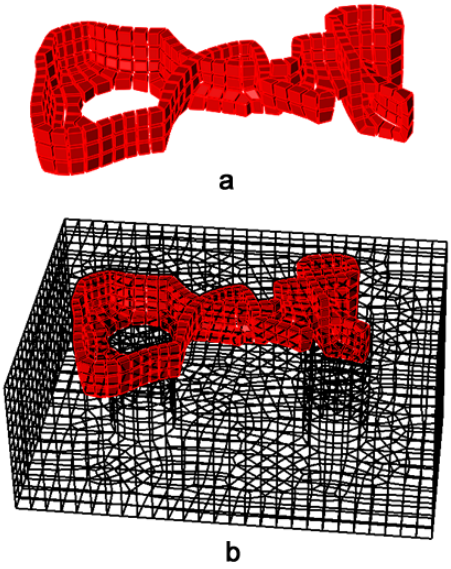

Figure 26: Sheet inflation: (a) the new sheet inflated from the quad set; (b) the new sheet in the hex mesh.

High node valence or edge valence will largely reduce the accuracy and efficiency of the analysis, or even make the mesh unable to be handled by the solver. The fun sheet matching algorithm proposed by Kowalski et al. [13] can help the hex mesh capture the geometric boundary by inserting fundamental sheets. This algorithm, however, can neither improve the node valences on the mesh boundary nor the edge valence near the mesh boundary. In this example, we will show how our approach can be used to reduce the high node valences and edge valences near the mesh boundary.

Figure 27(a) shows two nodes v_1 and v_2 with high valences. The valences of v_1 and v_2 are 6 and 7 respectively. Consequently, the edges inside the hex mesh that are adjacent to these two nodes also have high valences which are 6 and 7 respectively as shown in Fig. 27(b). It is usually unacceptable for node or edge valences to be larger than 5 near the boundary. Therefore, these high valences need to be reduced.

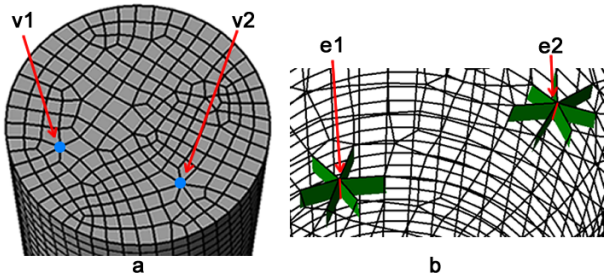

Figure 27: Nodes and edges with high valences: (a) v_1's valence is 6 and v_2's valence is 7; (b) v_1's adjacent edge e_1 has the valence of 6 and v_2's adjacent edge e_2 has the valence of 7.

To reduce the high valences by our approach, the user firstly select several edges on the mesh boundary that are adjacent to the two nodes and the local region as shown in Fig. 28(a). Our approach takes these edges as constraints, and then try to achieve the sheet inflation under the constraints. Figure 28(b) and Fig. 28(c) show the process of determination of the boundary loop, and the final boundary loop is shown in Fig. 28(d).

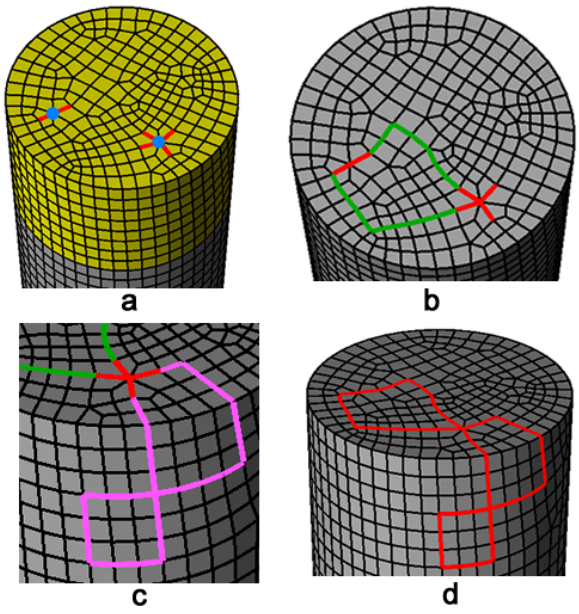

Figure 28: User-specified constraints and the determination of the boundary loop: (a) several boundary edges adjacent to v_1 and v_2 are selected as boundary constraints(red) and a set of hexahedra are selected as local region (yellow); (b) the constraint edges are firstly connected; (c) a new intersecting node is created; (d) the final boundary loop.

The quad set is then constructed through the procedures shown in Fig. 29. The variation of irregular degrees of the initial quad set is 184. The final optimized quad set is shown in Fig. 29(e) and its variation of irregular degrees is reduced to 159.

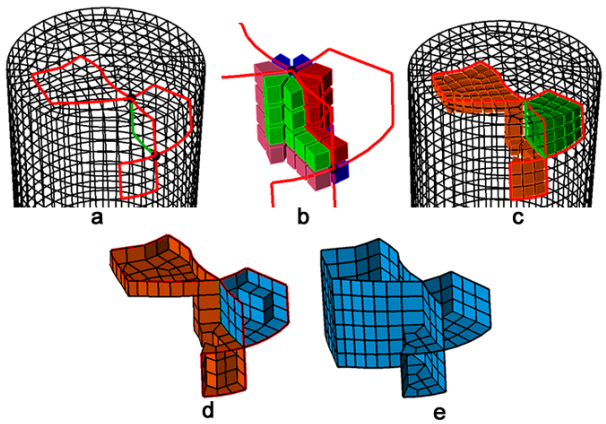

Figure 29: Process of the determination of the quad set: (a) the intersecting line is determined; (b) the int-4-hex-sets are constructed; (c) the merged hex sets; (d) the initial quad set; (e) the optimized quad set.

The sheet inflation is conducted after getting the quad set.

The new sheet is shown in Fig 30(a) and Fig. 30(b). The two nodes v_1 and v_2 are actually splitted into two nodes and four nodes respectively as shown in Fig. 30(c). The new edges splitted from e_1 and e_2 are shown in Fig. 30(b). There has no longer any nodes or edges with valences larger than 5.

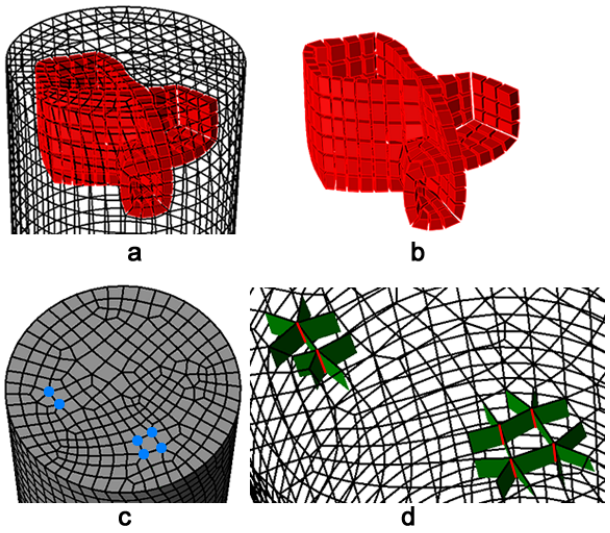

Figure 30: Results of high valences reduction: (a) the new sheet inflated from the quad set in the hex mesh; (b) the new sheet; (c) the new nodes with valences no larger than 5; (d) new edges with valences no larger than 5.

7. Conclusions and Future Work

In this paper, a new approach is proposed to achieving optimized complex sheet inflation under various constraints. Main features of our approach are summarized:

1. By using A* and max-flow-min-cut algorithms, the valid boundary loop of the quad set for sheet inflation is effectively determined, which satisfies the boundary constraints.
2. With intersecting nodes on the boundary loop being reasonably paired by using two templates, intersecting lines are validly constructed between each pair of nodes by using A* algorithm, and the int-4-hex-sets are determined around the intersecting lines, enabling our approach to effectively construct complex quad sets that intersect themselves more than once.
3. By using max-flow-min-cut algorithm, the valid initial quad set is effectively and efficiently determined within the local region specified by the user.
4. A chord-based optimization method is proposed which can effectively improve the quality of the quad set while avoiding the difficulty in optimizing the quad set as a whole.

The examples demonstrate that our approach can successfully generate complex sheets within a local region. These two examples also present two applications that our approach can be used: one is modifying the interfaces in mesh matching and the other is reducing node valences and edge valences to improve mesh quality.

The shortcomings of our approach and future work are listed below:

1. It is not very convenient to generate self-touching sheets. In some rare cases, self-touching sheets need to be generated. By combining other dual operations like column collapse and sheet extraction, our approach is able to create self-touching sheets. However, currently it is not very convenient. We will propose simpler solutions to generate self-touching sheets;
2. Currently the constraints can only be specified by boundary edges and hexahedra. However, sometimes the user needs to specify edges or quads inside the hex mesh to control the sheet inflation, e.g. improving the edge valences inside the hex mesh. Hence, we plan to adapt our approach to accept constraints specified inside the hex mesh.
